- Analogs: stellar, solar, terrestrial
- How to observe magnetic reconnection
- Conclusions

Impulsive phase and gradual phase: The Neupert Effect

Impulsive phase – primary energy release

- hard X-rays (10s of keV)
- white light, UV, μ waves - broad spectrum
- duration < few minutes
- intermittent and bursty time profile, 100ms
- **energy injection**

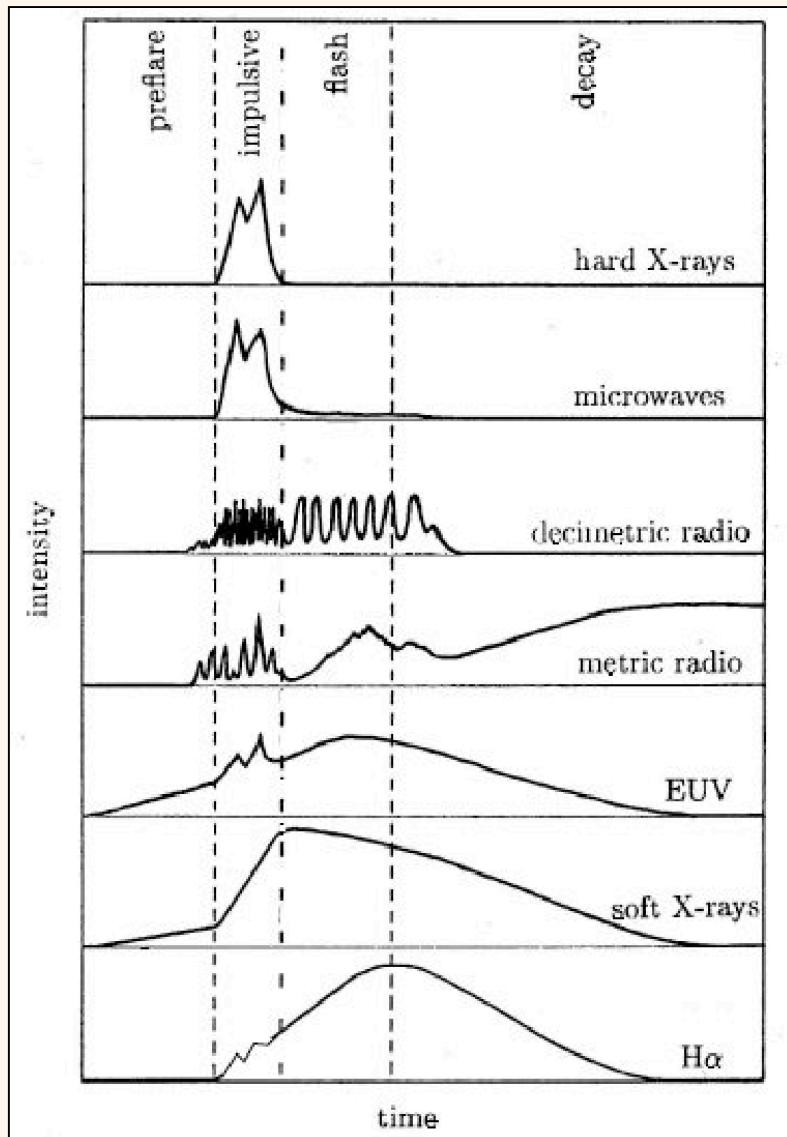

Gradual phase - response to input

- thermal emission ($kT \sim 0.1\text{-}1 \text{ keV}$)
- rise time \sim minutes
- coronal reservoir

Impulsive phase:

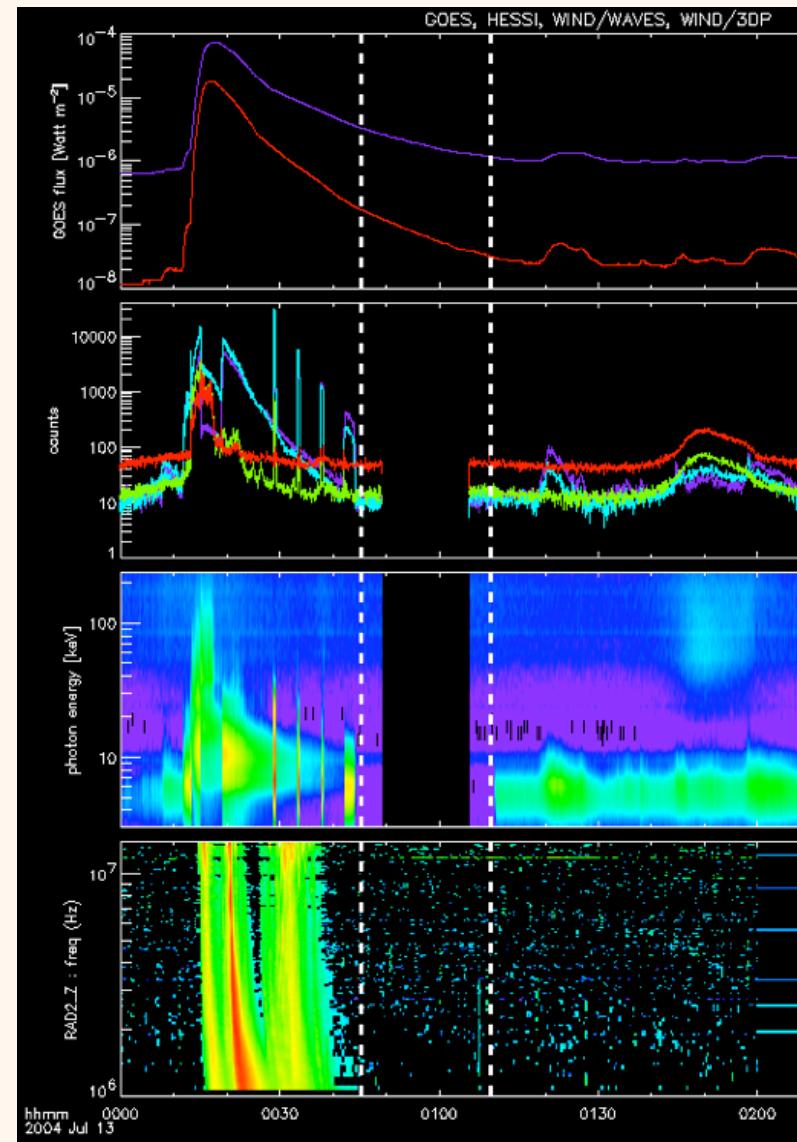

- > few tenths of the total flare energy released (up to 10^{32} ergs)
- Significant role for non-thermal electrons
- CME acceleration

Flare Phases

Benz, 2002

Boulder 23 July 2008

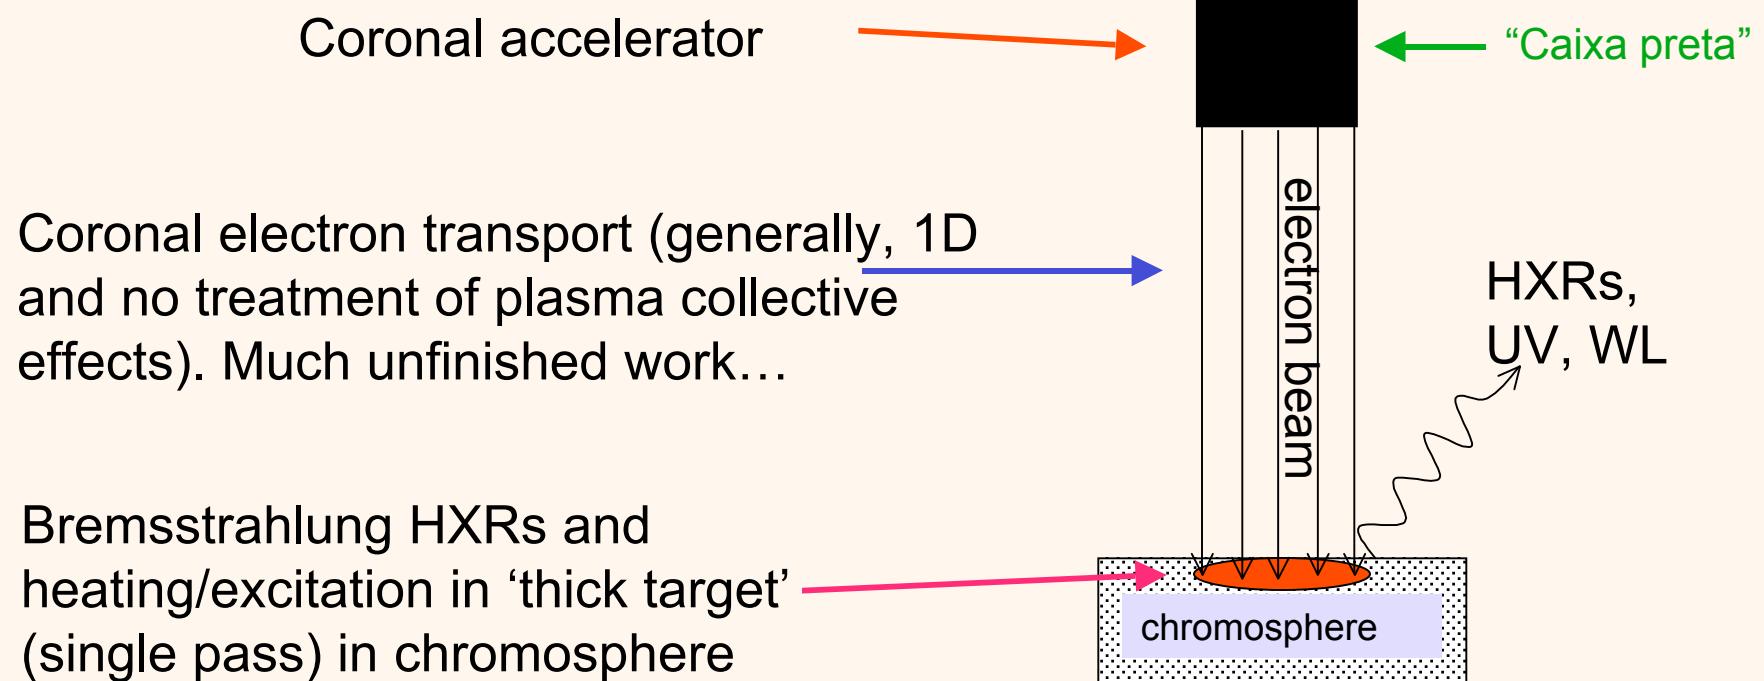

<http://sprg.ssl.berkeley.edu/~tohban/browser>
8/42

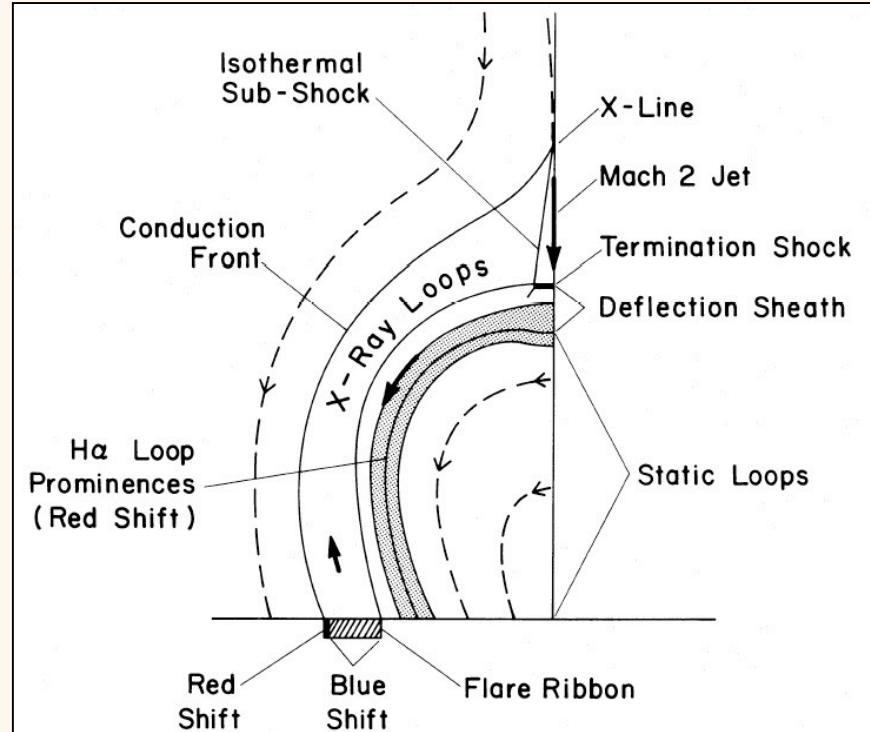

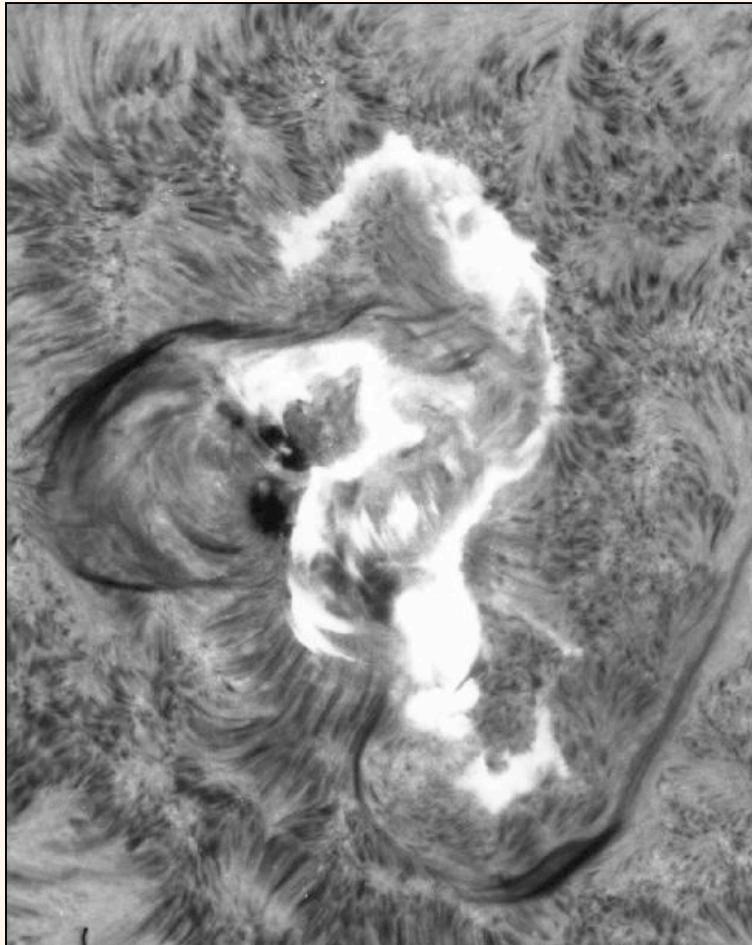

Impulsive Phase: the thick-target model

Collisional thick target model has dominated interpretations of flare non-thermal emission for > 3 decades.

Assumes hard X-ray emission is primarily electron-proton bremsstrahlung from electron beam, accelerated in the corona and stopped in chromosphere

Gradual phase: reconnection model

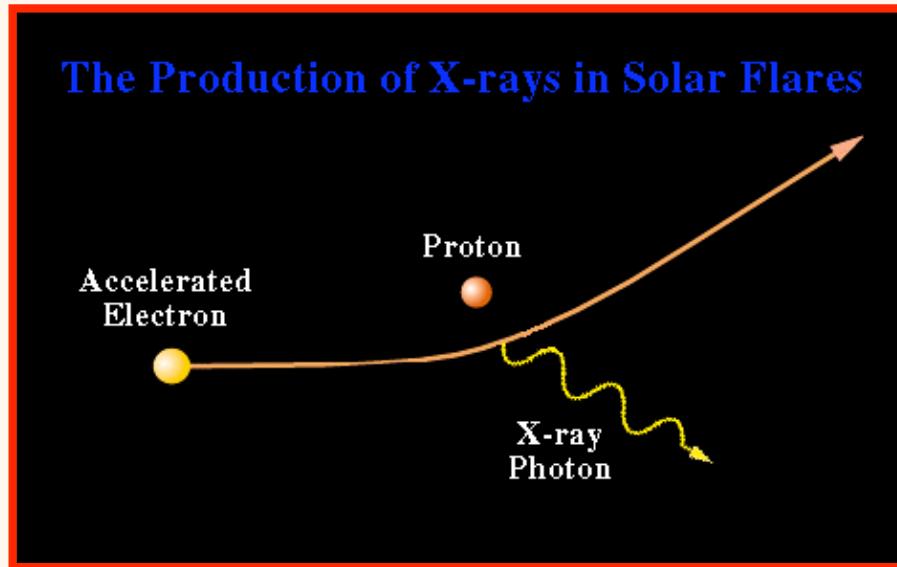

- Ribbon separation
- Loop temperature sequence
- Outer edge spectral signature
- Coronal cusp development
- Other signatures

Outline

- Flare Phases
- **Flare phenomena**
- Flare and CME energetics
- Analogs: stellar, solar, terrestrial
- How to observe magnetic reconnection
- Conclusions

X-Rays

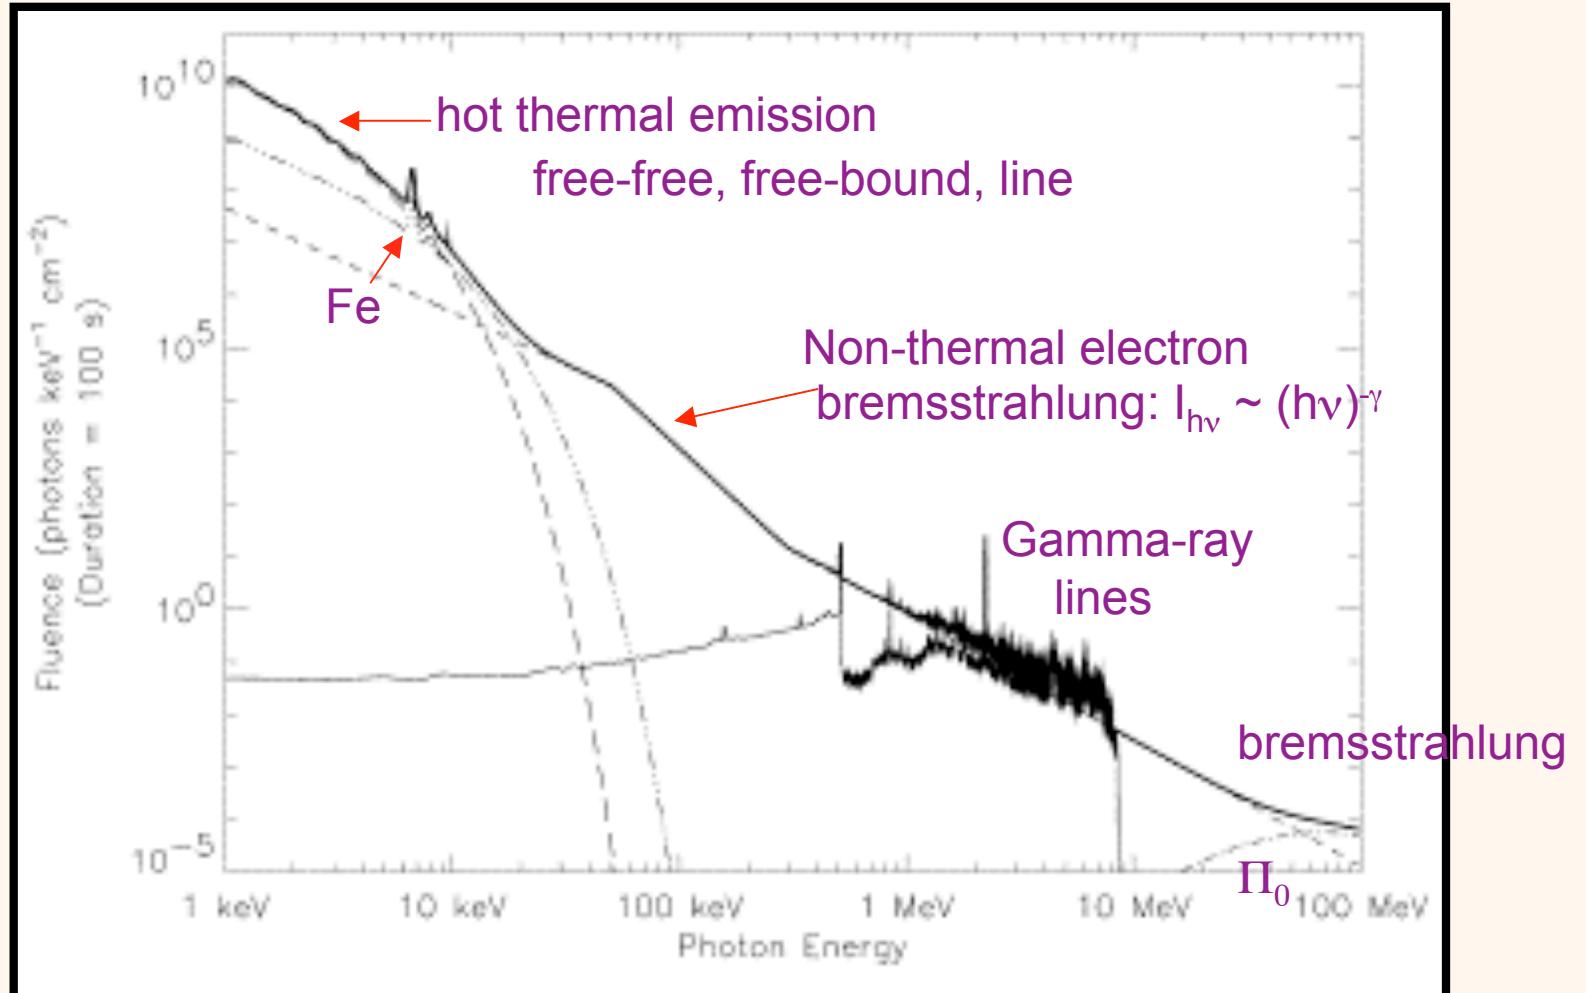

X-rays observed by (e.g.) RHESSI are primarily electron-proton bremsstrahlung from energetic electrons (>15 keV)

This is not a Feynman diagram!

- Non-thermal bremsstrahlung: $E_e \gg kT$ and photon spectrum $I_{h\nu} \sim (h\nu)^{-\gamma}$
 - not a significant energy loss: $\sim 10^{-5}$ of the energy radiated as X-rays
- Thermal bremsstrahlung: $E_e \sim kT$ and photon spectrum $I_{h\nu} \sim e^{-h\nu/kT}$
 - significant energy loss from electrons in a hot gas (1-10% of flare energy)
- Free-free, free-bound, and bound-bound (line) transitions

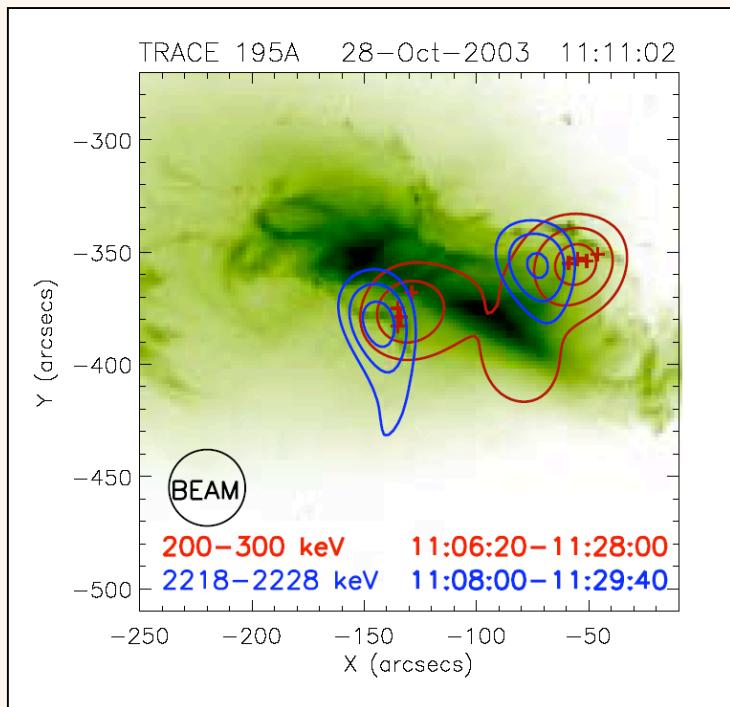

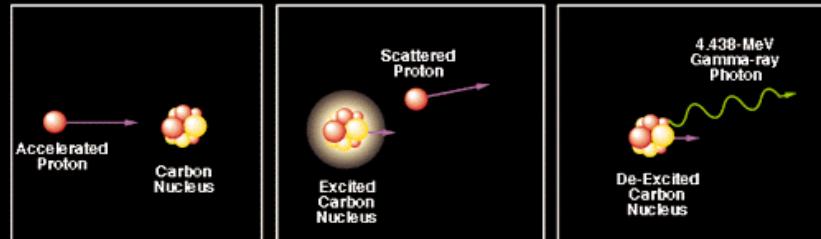

X-rays and gamma-rays

Gamma-rays

Nuclear de-excitation lines
caused by bombardment of
nuclei by 10-30 MeV protons;
de-excitation also via neutrons

Production of nuclear de-excitation lines

Hurford et al 2003

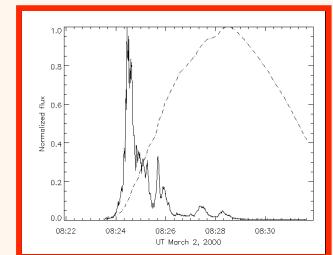

Boulder 23 July 2008

Neutron capture line at 2.23 MeV - $n(p,\gamma)D$
- shows location of 10s of MeV protons
- direct detection of neutrons also possible

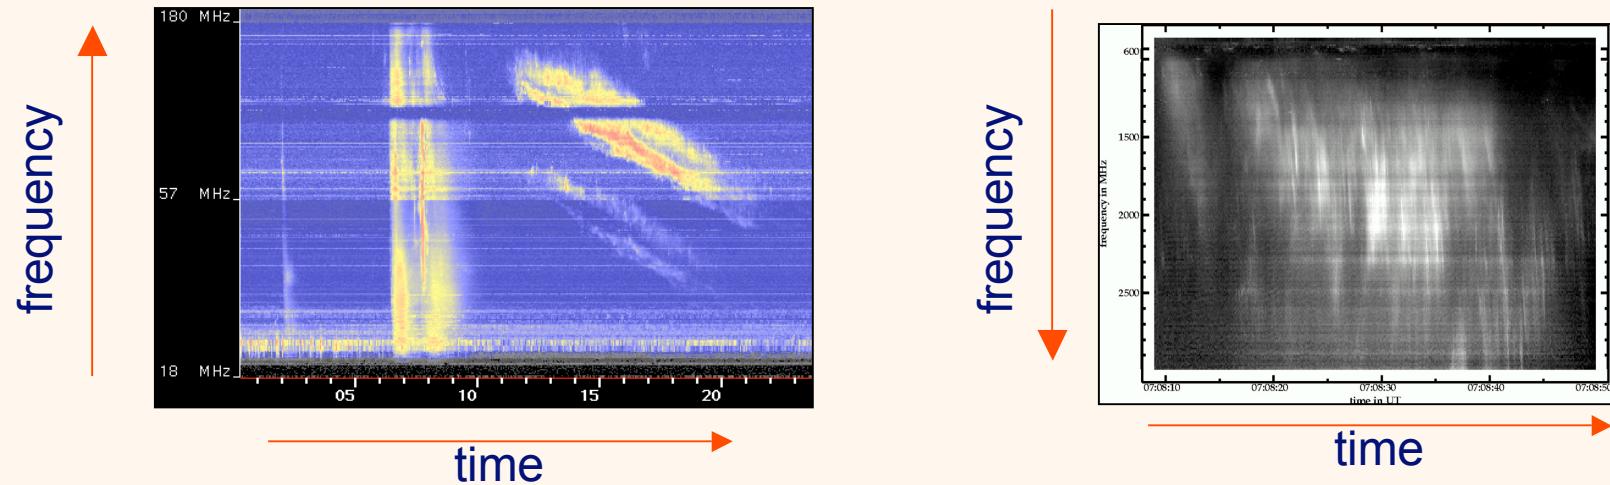

$\Pi_0 \rightarrow 2\gamma$ decay continuum shows ~100 MeV;
e⁺ annihilation line (511 kev) - complicated!

Radio waves

Basic opacity (hence emissivity) of the plasma is the **free-free process (bremsstrahlung)**, which depends on n_e , n_i , and T_e .

Fast electrons of the impulsive phase also emit **synchrotron emission**. This depends non-linearly on several parameters including \mathbf{B} .

Metric and decimetric Type III bursts are often **plasma radiation** produced by electron beams (from Langmuir waves at $f_p \sim 9000 n_e^{0.5}$ cgs).

Upward and downward-going *beams* sometimes observed, occurring at peak time of HXR emission. *Spectrograms* reveal the dynamics.

- **Energetics**
- Analogs: stellar, solar, terrestrial
- How to observe magnetic reconnection
- Conclusions

Thick target energetics / beam fluxes

In thick-target theory, can use HXR photon spectrum to calculate parent electron spectrum in chromosphere (Brown 1971).

The inferred requirement on electron number is - 10^{34} - 10^{36} electrons s^{-1} (ie coronal volume of 10^{27} cm^3 , $n = 10^9 \text{ e}^- \text{ cm}^{-3}$ should be emptied in $\sim 10\text{s}$)

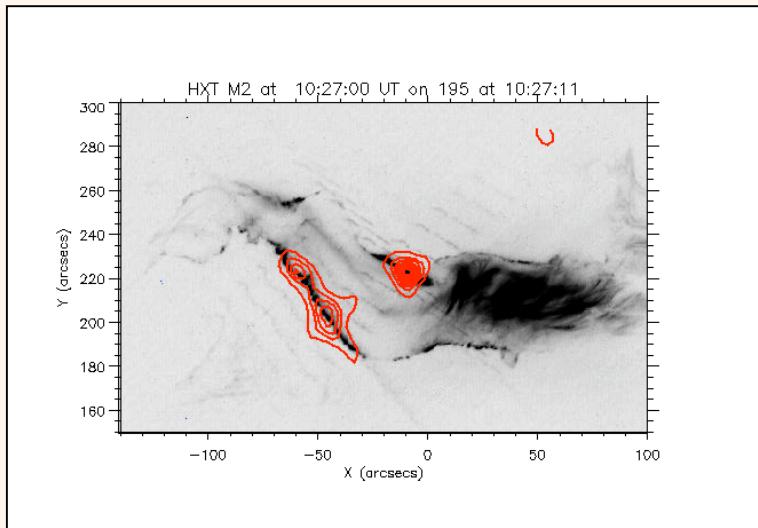

Beam density can be inferred using white-light footpoint areas as a proxy for beam ‘area’.

White light footpoint area $\sim 10^{17} \text{ cm}^2$

Ribbons in the impulsive phase

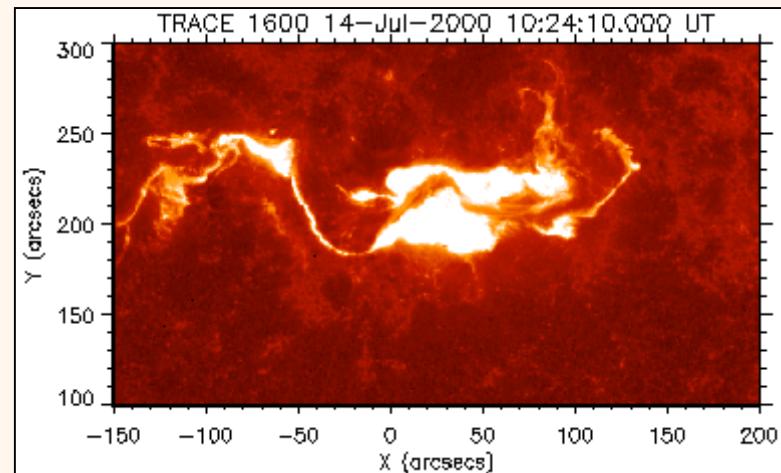

UV/EUV, H_α and (sometimes) optical emission demonstrate excitation of lower atmosphere

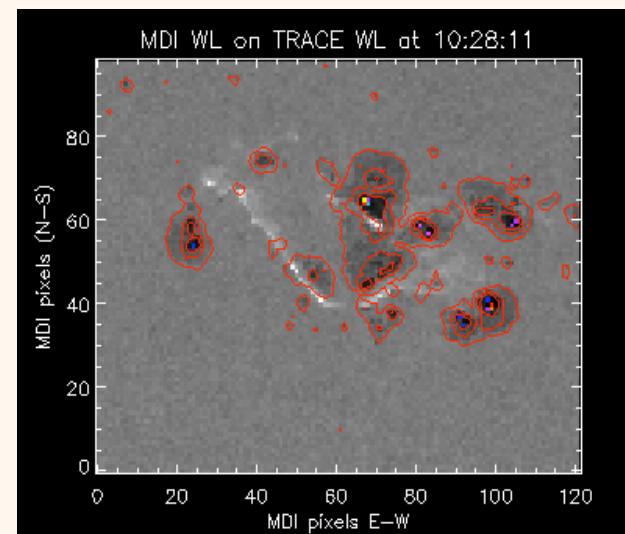

Yohkoh HXR contours on 195A emission

Optical/UV/EUV emission from conduction, “precipitation”, or waves

White-light luminosity can be directly measured.

1600A broadband emission

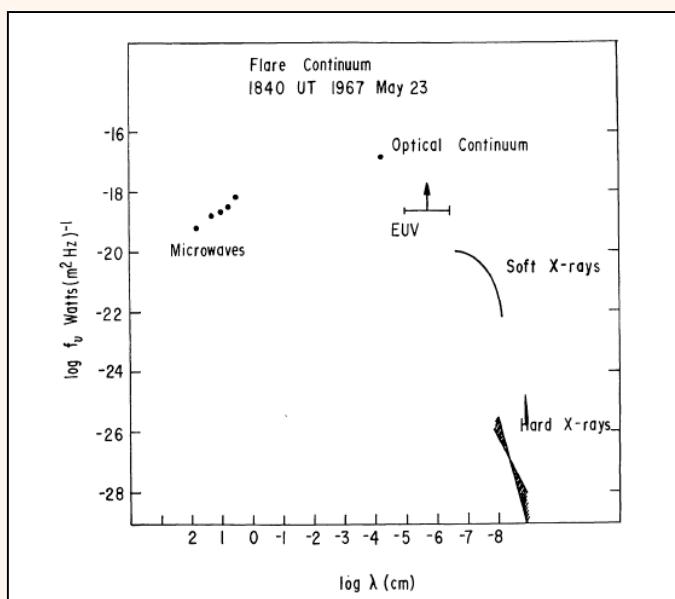

White-light footpoints

18<42

Role of ‘white light’ in total flare luminosity

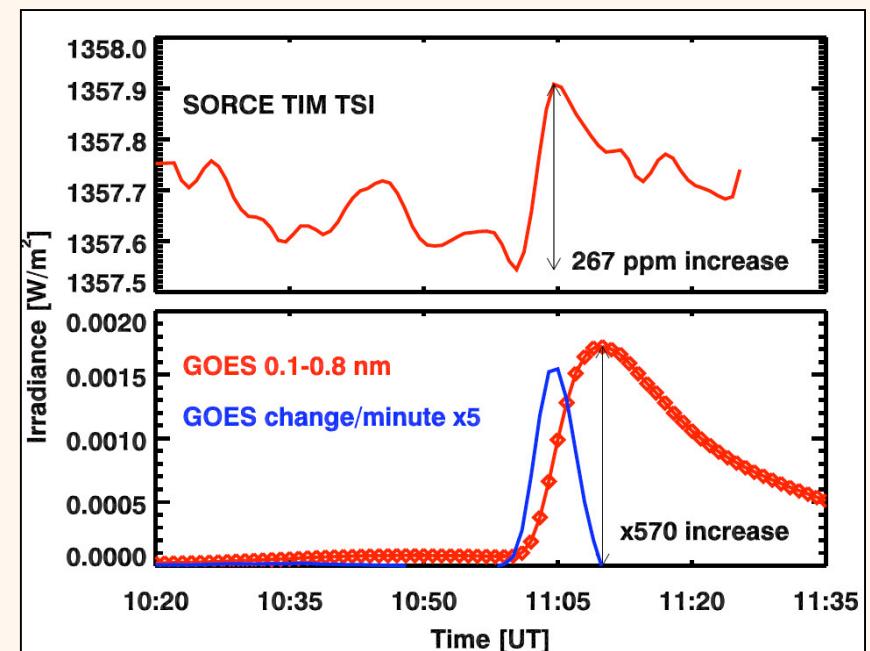

- Substantial fraction of total flare energy radiated in broadband UV-IR
- In Oct-Nov 2003 flares, integrated irradiance $\sim 3 - 6 \times 10^{32}$ erg
- Spectral modelling \Rightarrow 40-50% of this at $\lambda \geq 1900\text{\AA}$, ~ 100 times soft X-ray irradiance

Hudson 1972

Boulder 23 July 2008

Total Irradiance Monitor on SORCE

Woods et al. 2005

- TIM shows an impulsive component

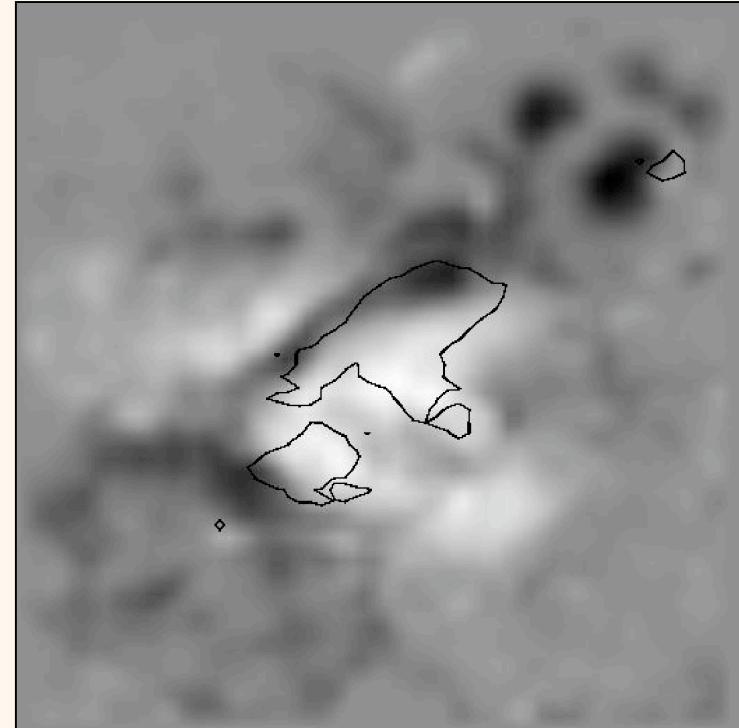

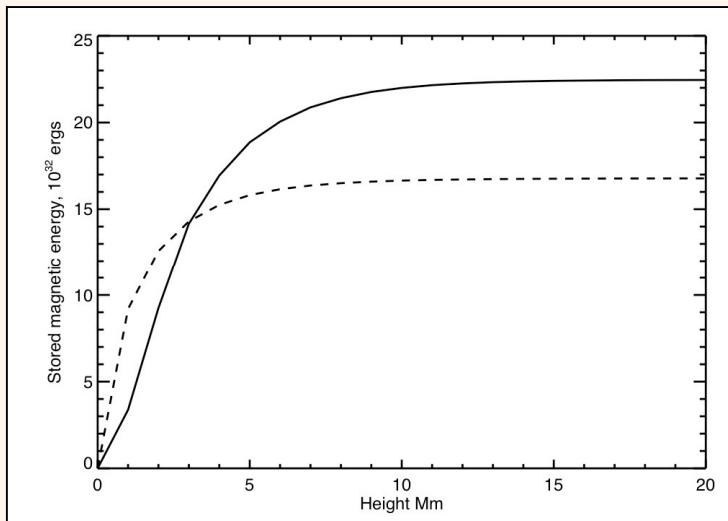

19<42

Particle acceleration in the impulsive phase

- The 10-100 keV electrons that emit hard X-rays contain a large fraction of the total flare energy. This is radiated in the UV and detected now in the total irradiance
- Although γ -ray observations are much less sensitive, it appears that 10-100 MeV proton acceleration is equally important
- The CME is accelerated at the impulsive phase, and its energy also may dissipate via “solar cosmic ray” acceleration in the accompanying shock wave
- **Particle acceleration is the most important theoretical problem in solar flare research**

Magnetic energy storage

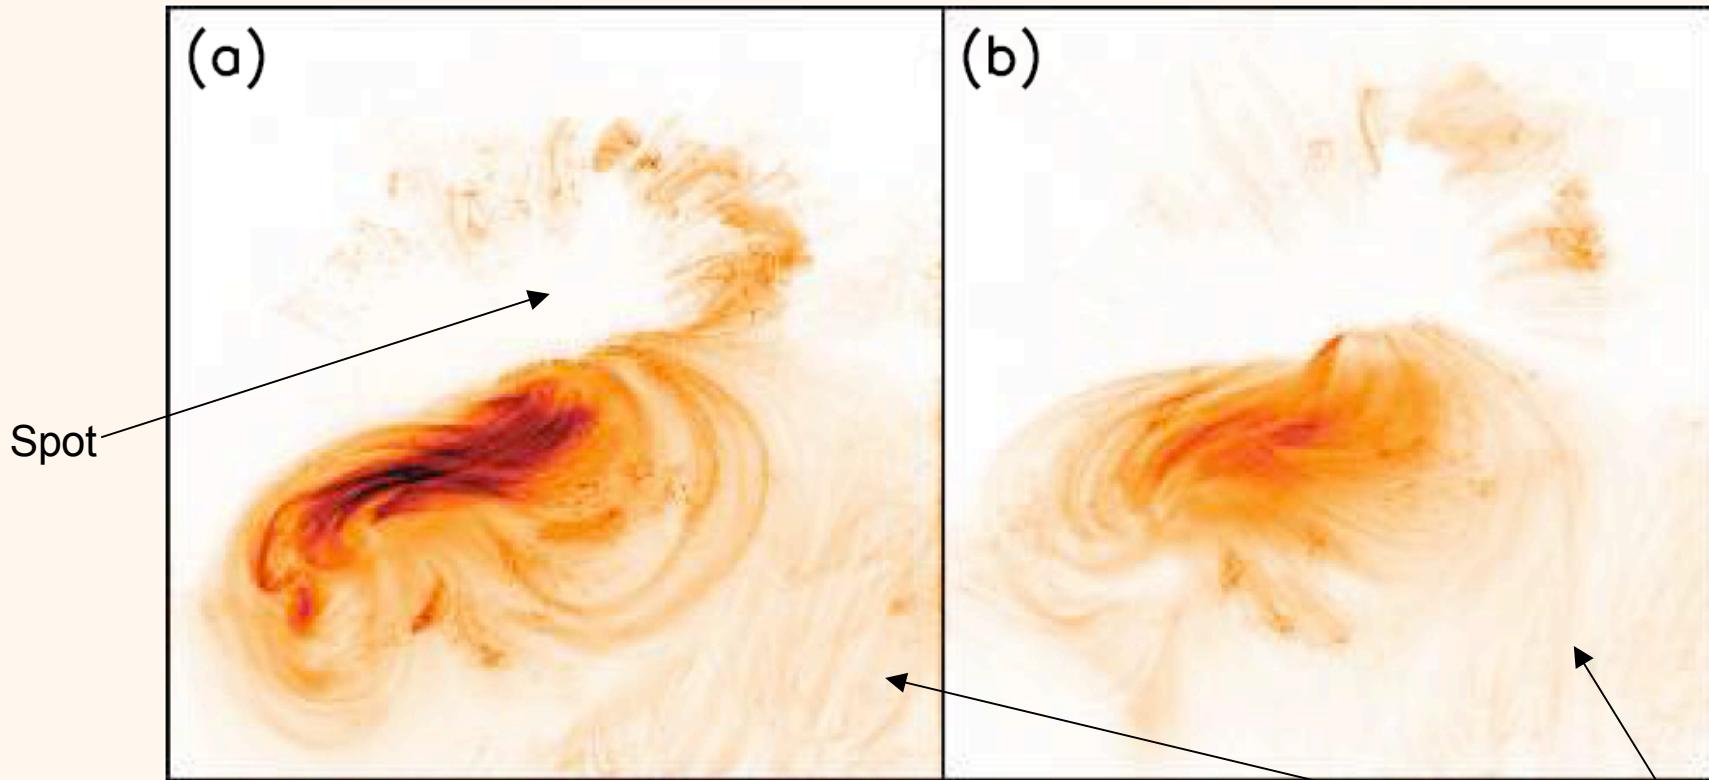

- Need to find locus of $\mathbf{B}^2/8\pi$
- Have force-free condition
 $\text{Curl}(\mathbf{B}) = \alpha(x,y)\mathbf{B}$
- Extrapolation of photospheric field observations
 - Potential ($\alpha = 1$)
 - Linear force-free (α constant)
 - Non-linear force-free NLFFF
(α general)

B_{los} in a solar active region and the 50% contour of \mathbf{B}^2

Integral distribution of stored energy (NLFFF vs potential) in height

Magnetic energy storage

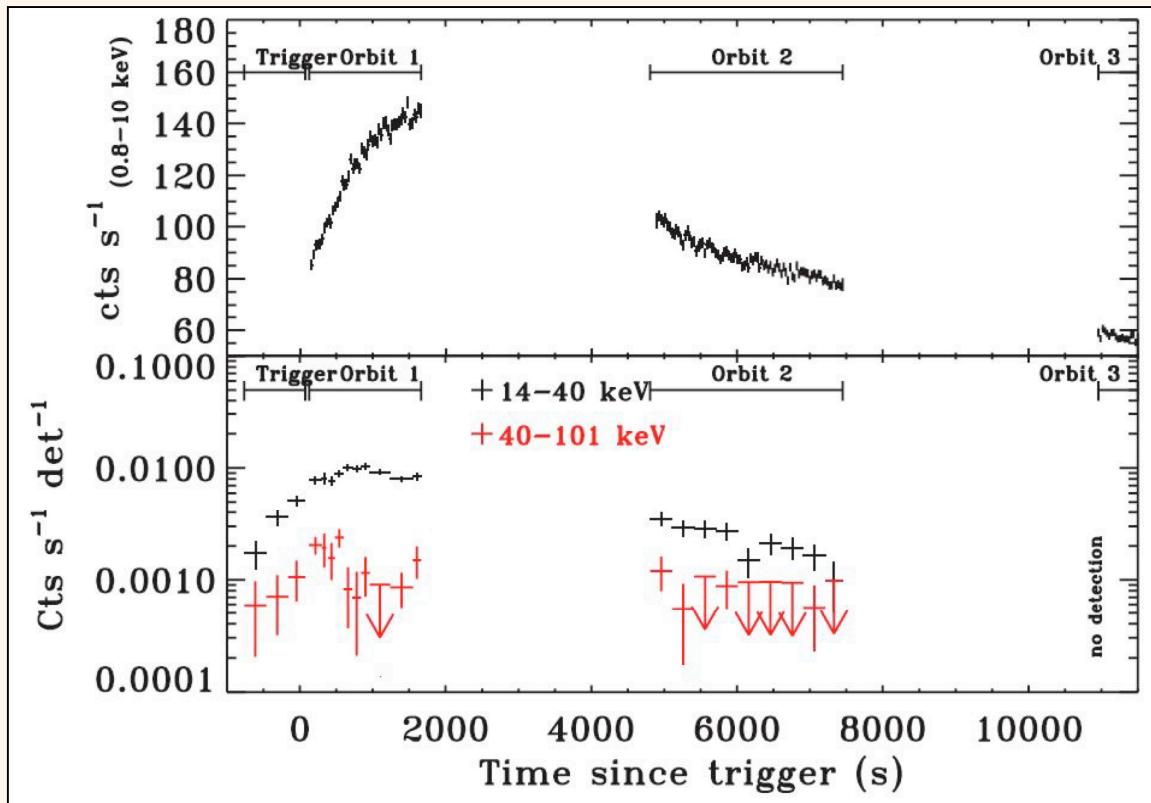

“Vertically integrated” electrical currents in an active region before (a) and after (b) an X-class flare (Schrijver et al., 2008). Note the apparent organization into a flux rope.

- **The magnetic energy in an active region is stored at low altitudes and may reside in a filament channel.**

Extreme stellar analogs

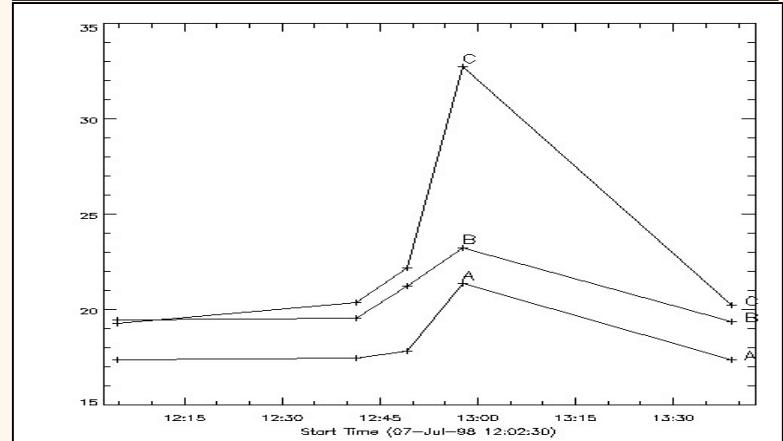

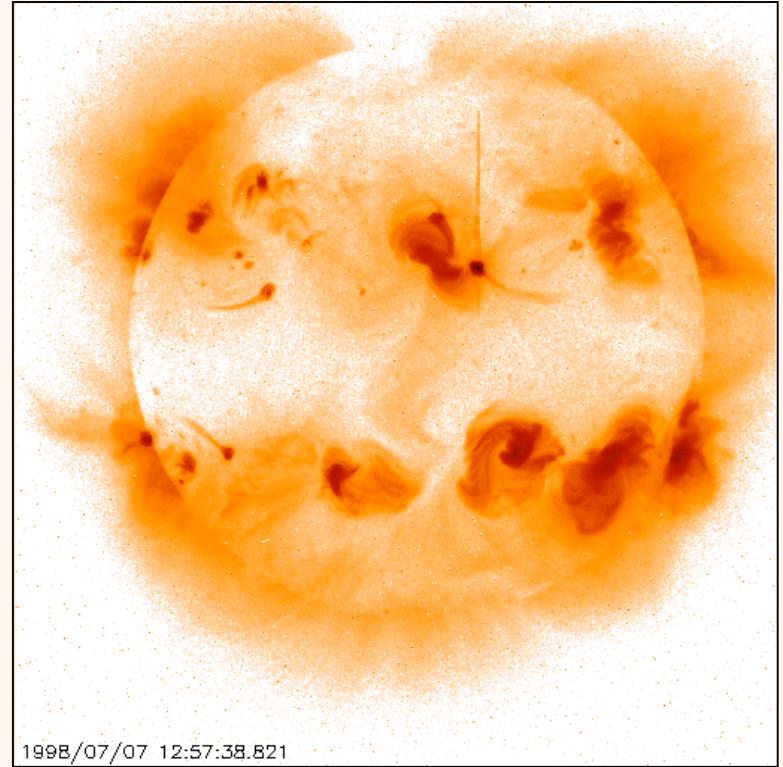

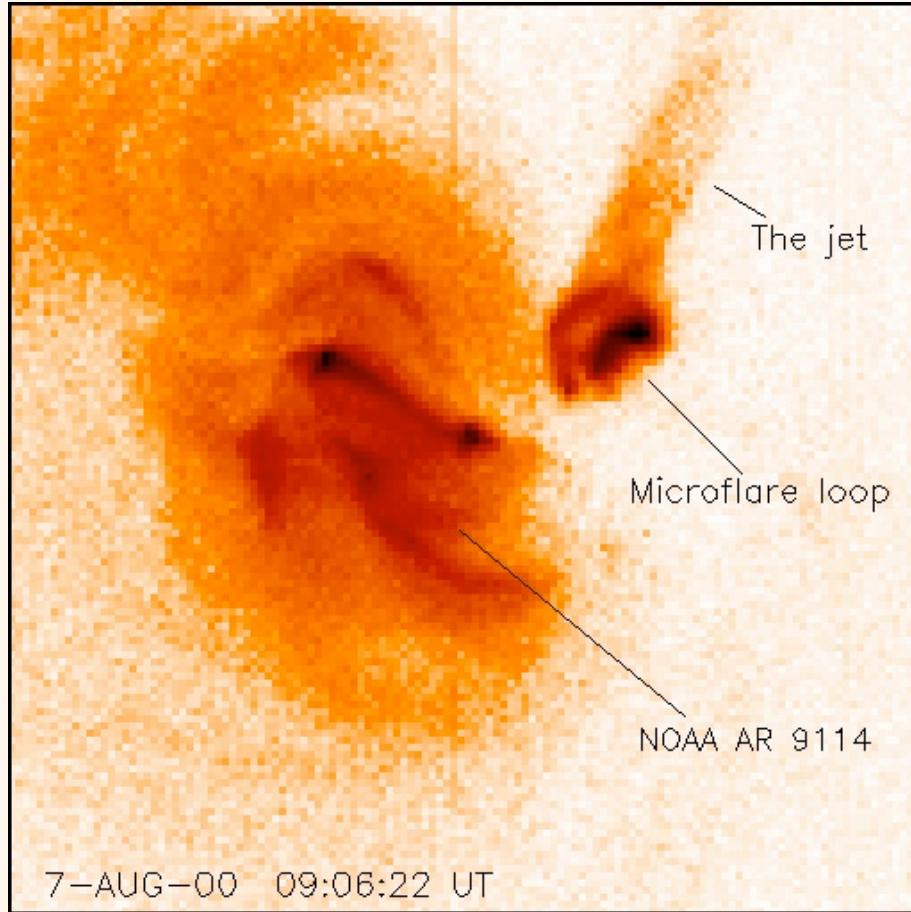

- A. “Magnetic duplicity” (Uchida & Sakurai)
- B. The X-wind model for T Tauri (Shu)
- C. Magnetars (Duncan)

These models all seek different ways to drive currents through the stellar environment and thereby to stress the magnetic field to form an energy reservoir

Are there other solar paradigms?

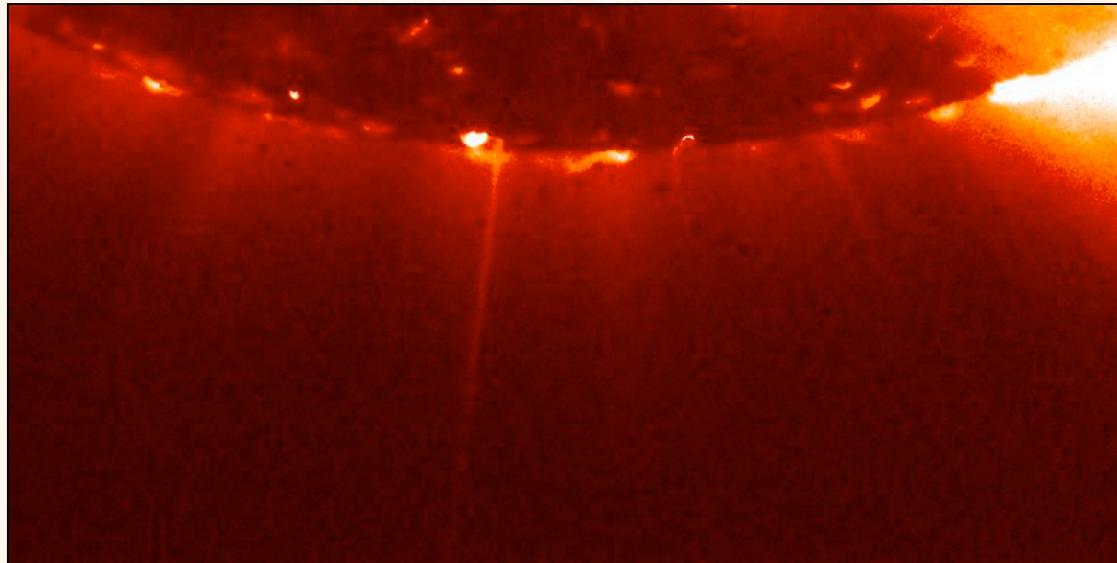

- X-ray jets
- Microflares/nanoflares
- “Extended flare” phenomena
- Masuda flare
- Non-thermal ejecta
- Shock waves
- Double layers
- Coronal thick-target events
- Impulse-response events

Microflares and nanoflares

RHESSI microflares, 2002-2007

Parker's nanoflare cartoon

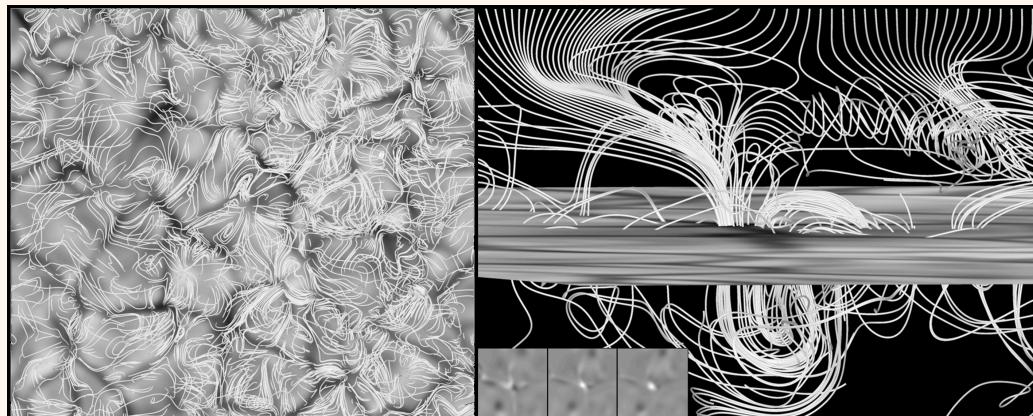

- Major flares have $\sim 10^{32}$ ergs total energy
- Microflares ($> 10^{26}$ ergs) occur in active regions
- Nanoflares are conjectural and weaker still

Outline

- Phases
- Phenomena
- Energetics
- Analogs: stellar, solar, terrestrial
- **How to observe magnetic reconnection**
- Conclusions

What do we mean by “magnetic reconnection”?

- The solar corona has **low plasma beta**:
 $\text{beta} = 2n\kappa T/(B^2/8\pi)$
- It appears to have a **cellular structure**, with magnetic domains separated by **current sheets**
- A flare may be associated with a restructuring of such **domains**
- The **microphysics** can be studied in the laboratory and in space plasmas

Magnetopause: Frey et al. 2003

Coronal acceleration?

'Volumetric' acceleration:

Wave-particle turbulence (e.g. Larosa et al, Miller et al,
Petrosian)

Stochastic current sheets (e.g. Turkmani et al)

Collapsing traps (e.g. Somov & Bogachev)

Betatron acceleration (e.g. Brown-Hoyng, Karlicky-Kosugi)

Diffusive shock or shock drift acceleration (e.g. Tsuneta &
Naito, Mann et al)

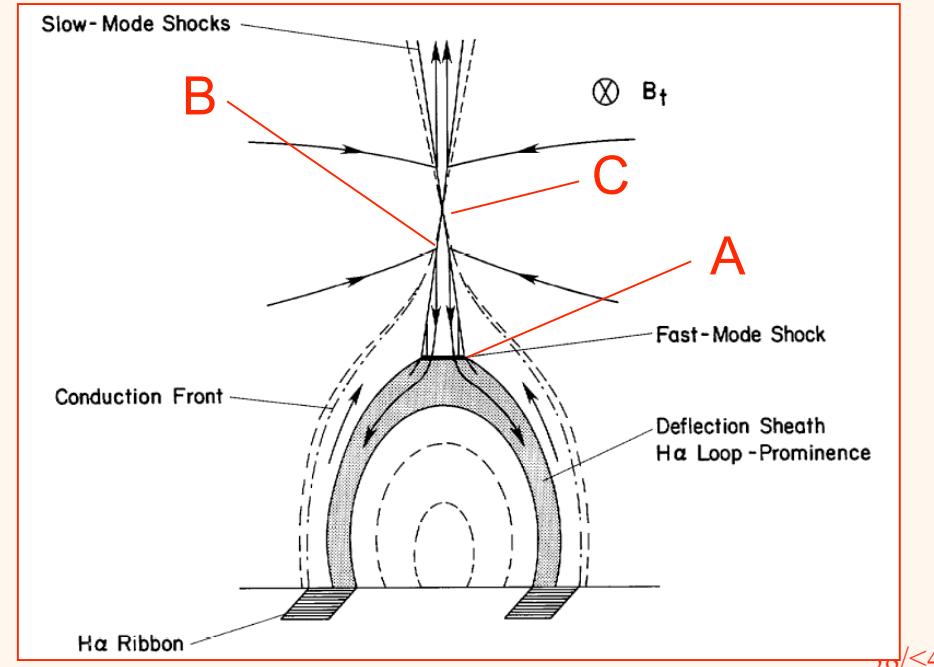

Reconnecting X-line or current-sheet acceleration

Multiple X-lines/islands (e.g. Kliem, Drake)

Single macroscopic current sheet (e.g. Litvinenko &
Somov, Somov & Kosugi)

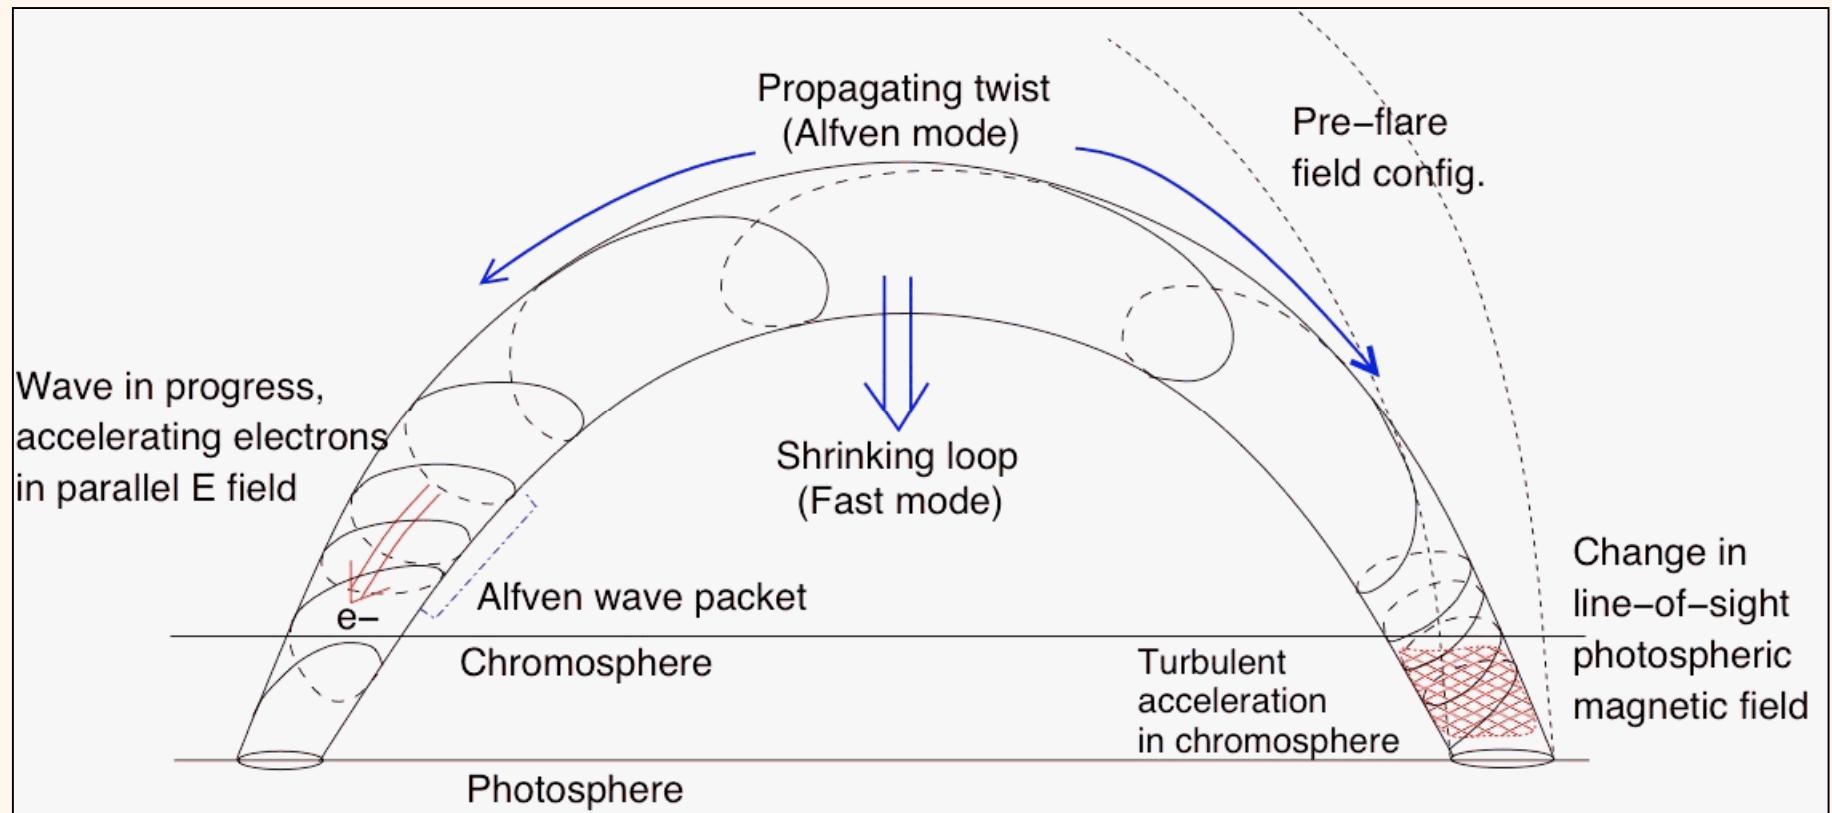

Problems for coronal acceleration

- Location (fast shock A, slow shock B, current sheet C - are any of these real?)
- The “number problem” - where to get the particles?
- How to get “flare particles” into the heliosphere?
- Beam dynamics - return currents and inductive effects
